Category:Year of introduction missing Category:2016 software Category:Windows-only software in the subgroup of younger patients ( $\leq 50$  years). The mGPS remained stable after treatment initiation, and high mGPS was more likely in older patients. As previously demonstrated \[@B3\], one-third of patients with advanced disease had two or more organ-related comorbidities (cardiovascular disease, diabetes, hypertension, chronic lung disease, and renal dysfunction). Although there was an increase in the number of comorbidities following treatment initiation, which is a potential confounding factor, the likelihood of developing new comorbidities after treatment initiation was significantly higher in patients with mGPS-1 and mGPS-2 than in those with mGPS-0/1. Based on these findings, we suggest that physicians should be aware of the association between mGPS and the risk of developing new comorbidities after treatment initiation. Our data revealed that elderly patients with mGPS-1 and mGPS-2 after treatment initiation were not more likely to develop new organ-related comorbidities than patients with mGPS-0/1. These data indicated that the prognostic value of the mGPS in patients with mGPS-1 or mGPS-2 appeared to be lower in elderly patients. The biological processes in elderly patients appear to be different from those of young patients \[@B17\]. The aging process may influence physiological functions of the liver \[@B18\] and immune system \[@B19\] and lead to a reduction in lymphocyte counts \[@B20\]. It is possible that the impact of the mGPS on the development of new comorbidities in elderly patients was limited. Thus, further studies investigating the association between the mGPS and the risk of developing new organ-related comorbidities in elderly patients are needed. The present study has several limitations. First, as a retrospective analysis, this study had the possibility of potential selection bias. Second, as previously reported \[@B3\], patients with mGPS- 2d92ce491b
