Category: Electromagnetic simulation This invention relates generally to a spinal fixation device, and more specifically to a spinal fixation device for longitudinally joining and/or maintaining a pair of spinal elements in a desired spatial relationship. In certain spinal disorders, such as degenerative disc disease, disc herniation, osteoporosis and osteoarthritis, the spinal disc(s) that resides between the vertebrae may deteriorate. These spinal discs may become thinner and result in a loss of structural rigidity. Furthermore, the vertebrae may tend to move in response to the deterioration of the discs and the overall loss of disc height. This phenomena, known as "spondylolisthesis," may also be the result of an injury. Spondylolisthesis can be the result of a direct fracture or tear of the pars interarticularis and results in a defect in the structure and function of the spine.

Furthermore, in conditions such as spinal stenosis, the spinal canal or lateral recess may become filled or filled with bone and/or soft tissue, resulting in compression of the spinal cord and nerve roots. One known method of stabilizing a portion of the spine is to fuse the spine. In a typical spinal fusion procedure, the disc is removed and the vertebrae are permitted to move with respect to one another. A suitable biocompatible implant, such as a bone plate having a number of apertures therethrough is then inserted. By positioning the bone plate so that it holds one or more of the vertebrae in a desired spatial relationship, the spine can be fused. However, it is difficult to precisely locate the bone plate to adequately stabilize the spinal segments and, once inserted, bone plates are bulky and can cause nerve irritation and can be a distraction to normal bone and tissue ingrowth. More recently, the use of spinal implants have been popularized to correct spinal defects. In these procedures, elongated spinal implants, for example rods, are surgically placed over and across spinal column segments that are to be fused. The spinal implants may either intersect or be positioned in close proximity to the neural elements such that the implants restrict or even prevent movement of the neural elements. Typically, an elongated spinal implant is placed along or with a pair of spinal rods and serve as additional structural support to help stabilize the pair of spinal rods. These elongated spinal implants have proven to be highly useful in stabilizing the spine and promoting bony fusion. In a typical
